

## Research on Abortion and Preterm Birth

Prevent Preterm thanks Elizabeth Doecke, M.D. candidate 2016, for her immense contributions to this report.

The Guttmacher Institute, an abortion think tank, has conducted surveys about the reasons women have abortions. Most survey respondents said that they had not completed their childbearing. They did not feel prepared for parenthood at the time of the abortion—typically for financial reasons—but were open to parenthood in the future. In fact, some interviewees said that they were having abortions because they wanted to set up an ideal situation in which to parent the future sons and daughters they had not yet conceived.

These statements show a tragic lack of awareness of abortion's long-term consequences. Abortion is a risk factor for preterm (premature) birth in later pregnancies. A child born preterm may face lifelong health problems. And ironically, those health problems are often expensive, creating a financial burden on the family—precisely the outcome the mother sought to avoid by having an abortion.

The exact reason that abortion increases the risk for preterm birth remains unknown. Researchers have suggested several possibilities, including damage to the cervix that causes it to be weaker,<sup>1</sup> increased risk of infection in the uterus during pregnancy,<sup>2</sup> and increased risk of bleeding during pregnancy.<sup>3</sup> More studies are needed. The existence of a link, however, is well-established.

This document summarizes the research on abortion and preterm birth so that women can make informed health decisions for themselves and their families. Prevent Preterm believes that every woman deserves this information, regardless of whether or not she has a medical background. Therefore, Prevent Preterm has done everything possible to make this medical research accessible to laypeople, without sacrificing accuracy.<sup>4</sup>

<sup>4</sup> Some articles that explore the link between abortion and preterm birth have not been listed in this document due to their inaccessibility. For instance, they may be written in a foreign language or unavailable in online databases.

## How to read the table and what to look for

Prevent Preterm has compiled the medical research into a table, beginning on page 4. As you read, bear in mind that the best studies are those that:

- 1) **Are peer-reviewed:** One study (MacDonald 2009) was undertaken as part of a Master of Public Health Program at Virginia Commonwealth University, and would have been reviewed by senior researchers within the field. All remaining studies in this document come from peer-reviewed journals, where the articles are assessed for accuracy and reliability by other researchers.
- 2) **Have a low p-value:** The value of p is a statistical measure of how reliable a study is. Simply put, studies with many participants and striking results are more reliable than those with few participants and weak results. If p is less than .05, the study is said to be “statistically significant,” which means that its results are unlikely to have been caused by random chance. Many of the studies in this document are statistically significant. Studies with non-significant results have also been included, as the cumulative number of these studies suggests a trend exists that may show a relationship between abortion and preterm birth.
- 3) **Address alternative explanations for the results:** If a study finds that women who have had abortions are more likely to give birth preterm than women who have not had abortions, that alone is not proof that abortion causes preterm birth. Other explanations are possible. For example, we know that low-income women are more likely to have abortions. Low-income women are also less likely to receive prenatal care, and lack of prenatal care is a risk factor for preterm birth. Therefore, low income could be the real cause. In this example, low income is what is called a “confounding factor.” Age is another example; older women are more likely to give birth preterm, and also more likely to have had an abortion at some point just by virtue of the fact that they have lived longer and have a longer history of being able to get pregnant.

To avoid having results tainted by confounding factors, researchers can do one (or both) of two things. First, they can try to create a control (comparison) group that is very similar to the study group; for instance, by comparing low-income 30-year-old women who have had abortions to low-income 30-year-old women who have not had abortions. That becomes unwieldy, however, as you add confounding factors. (Some of the studies in this document address ten or more confounding factors!) The second option is to employ a mathematical formula to “control for” other possibilities; these are referred to as “controlled variables.”

Studies with many controlled variables allow you to engage in a process of elimination. If alternative explanations have been addressed, abortion is more likely to be the cause of the increased risk for preterm birth.

- 4) **Show a “dose-response” relationship:** If a study finds a “dose-response” relationship, this means that the risk of preterm birth increases with each abortion. A woman who has never had an abortion faces the least risk, a woman who has had one abortion faces an increased risk, and a woman who has had multiple abortions faces the greatest risk.

Note also that in a few studies, the researchers actually set out to study a different topic and made findings about abortion along the way. For example, in the A. E. Curry et al. study on page 19, the topic of study was the relationship between preterm birth and inflammation. The fact that studies on other topics corroborate the abortion-preterm birth link makes it unlikely that these results are merely due to a researcher’s political bias.

The table includes six columns:

- 1) **Article Information:** This column contains the title and authors of each study, along with the date when it was published and the journal in which it was published. If you have access to subscription medical journals (through a college library, for example), you can use this information to access the full text of the article. The articles are ordered from newest to oldest.
- 2) **Results:** This column shows the factor being examined (e.g. induced abortion or spontaneous abortion) and the increased risk or odds of the outcome happening (e.g. induced preterm birth, spontaneous preterm birth, or premature rupture of membranes).

Some studies combine induced abortions and spontaneous abortions as one factor. "Spontaneous abortion" is the medical term for miscarriages; it is not what laypeople think of as "abortion." However, women who suffer miscarriage sometimes have to undergo a dilation and curettage procedure to remove the remains of the miscarried child.<sup>5</sup> Dilation and curettage is also used as an abortion procedure when the fetus is alive. Accordingly, if a researcher is specifically interested in the risks associated with dilation and curettage abortion, it is unsurprising that spontaneous abortions would also be included.

The outcomes studied include both spontaneous and induced preterm birth, as well as premature rupture of membranes (when the waters break early). An induced preterm birth occurs when the woman is given medication to cause early labor, while a spontaneous preterm birth is when labor happens on its own. Induced preterm birth is often done for medically necessary reasons that may be related to prior abortions—such as premature rupture of membranes, infection inside the uterus or the placenta becoming unattached.<sup>6</sup> Premature rupture of membranes is closely related to preterm birth; it usually leads to delivery within one week.<sup>7</sup>

- 3) **Study Description & Other Comments:** This column contains information on how the study was carried out and what data was collected. It also contains any extra information that might be helpful in understanding the result, such as whether the study found a dose-response relationship (see above).
- 4) **Study Group:** This column describes the study group and gives the number of people in this group.
- 5) **Control Group:** This column describes the control group and gives the number of people in this group.
- 6) **Controlled variables or confounding factors adjusted for:** This column lists the alternative explanations addressed in the study (see above).

## Glossary of Terms

**Parity** is the number of times a woman has given birth. A woman who is parity one has given birth once, a woman who is parity two has given birth twice, etc. It includes stillbirths but not early miscarriages or abortions.

**Gravidity** is the number of times a woman has been pregnant, regardless of whether the pregnancy or pregnancies ended in birth, stillbirth, abortion, or miscarriage.

A **registry study** is an observational study in which researchers gather information but do not make any changes to how the study and/or control group are being treated.

In a **meta-analysis**, sometimes called a "study of studies," the results from several different studies are gathered together and mathematically analysed to give one overall result.

In a **literature review**, the published knowledge in a particular area is collected and reviewed.

A **medical abortion** is one that is performed using medication rather than surgery. **Mifepristone** is a medication commonly used in medical abortions.
